Percutaneous coronary interventions (PCI) with or without stents and coronary artery bypass graft surgery (CABG) are the two broad categories of interventions for mechanical revascularization of atherosclerotic coronary arteries in patients with coronary artery disease (CAD). The choice of revascularization procedure is often determined by coronary anatomy and the technical feasibility of either PCI or CABG. Therefore the clinical dilemma pertains to patients in whom both procedures are technically feasible and whose coronary disease is neither too limited nor too extensive. Generally, both approaches would be clinically relevant for patients with single-vessel disease of the proximal left anterior descending artery, most types of two-vessel disease, as well as patients with three-vessel disease that is not particularly extensive. Because PCI and CABG differ in their procedural risk and their initial and downstream costs, assessing their comparative effectiveness and safety is of great interest. PCI and CABG have already been compared in several randomized controlled trials (RCTs) and analyses of large clinical registries. The aim of this report is to identify needs for future research in the comparison between PCI and CABG. We use as a basis the 2007 comparative effectiveness report (CER) by the Stanford University of California at San Francisco Evidence-based Practice Center (StanfordUCSF EPC) that assessed PCI vs. CABG for coronary artery disease. The report summarized evidence published through 2006 to address the following key questions: Key Question 1a: In patients with ischemic heart disease and angiographically proven single- or multiple-vessel disease, what is the comparative effectiveness of PCI compared to CABG in reducing the occurrence of adverse objective outcomes and improving subjective outcomes Key Question 1b: Over what period are the comparative benefits of PCI and CABG...
